

**PISTOL GRIP ELECTROSURGICAL PENCIL WITH
MANUAL ASPIRATOR/IRRIGATOR AND METHODS OF USING THE SAME**

BACKGROUND

1. Technical Field

The present disclosure relates generally to electrosurgical instruments and, more particularly, to an electrosurgical pencil having an integral manual aspirator/irrigator. The present disclosure is also directed to methods of using the electrosurgical pencils disclosed herein.

2. Background of Related Art

Electrosurgical instruments have become widely used by surgeons in recent years. Accordingly, a need has developed for equipment and instruments which are easy to handle, are reliable and are safe in an operating environment. By and large, most electrosurgical instruments are hand-held instruments, e.g., an electrosurgical pencil, which transfer radio-frequency (RF) electrical energy to a tissue site. The electrosurgical energy is returned to the electrosurgical source via a return electrode pad positioned under a patient (i.e., a monopolar system configuration) or a smaller return electrode positionable in bodily contact with or immediately adjacent to the surgical site (i.e., a bipolar system configuration). The waveforms produced by the RF

source yield a predetermined electrosurgical effect known generally as electrosurgical fulguration.

In particular, electrosurgical fulguration includes the application of electric spark to biological tissue, for example, human flesh or the tissue of internal organs, without significant cutting. The spark is produced by bursts of radio-frequency electrical energy generated from an appropriate electrosurgical generator. Generally, fulguration is used to coagulate, cut or blend body tissue. Coagulation is defined as a process of desiccating tissue wherein the tissue cells are ruptured and dehydrated/dried. Electrosurgical cutting, on the other hand, includes applying an electrical spark to tissue in order to produce a cutting or dividing effect. Blending includes the function of cutting combined with the production of a hemostasis effect.

As used herein the term "electrosurgical pencil" is intended to include instruments which have a handpiece which is attached to an active electrode and which is used to cauterize, coagulate, blend and/or cut tissue. Typically, the electrosurgical pencil may be operated by a handswitch or a foot switch. The active electrode is an electrically conducting element which is usually elongated and may be in the form of a thin flat blade with a pointed or rounded distal end. Alternatively, the active electrode may include an elongated narrow cylindrical needle which is solid or hollow with a flat, rounded, pointed or slanted distal end. Typically electrodes of this sort are known in the art as "blade", "loop" or "snare", "needle" or "ball" electrodes.

As mentioned above, the handpiece of the electrosurgical pencil is connected to a suitable electrosurgical energy source (e.g., generator) which produces the radio-frequency electrical energy necessary for the operation of the electrosurgical pencil. In general, when an operation is performed on a patient with an electrosurgical pencil, electrical energy from the electrosurgical generator is conducted through the active electrode to the tissue at the site of the operation and then through the patient to a return electrode. The return electrode is typically placed at a convenient place on the patient's body and is attached to the generator by a conductive material.

During surgery, these electrosurgical instruments generally produce a plume (typically of smoke) when organic material (e.g., the tissue of the patient) is being vaporized. The plume created by the vaporization of the organic material is offensive in the operating room and especially if inhaled.

In the typical technique, the plume is aspirated by a conventional suction tube being held near the site of the electrosurgical procedure by an assistant. Unfortunately, this method inefficiently requires the full time attention of the assistant and the placement of the often bulky suction tube in the operative field of the surgeon thus obstructing the surgeon's view. Additionally, these suction tubes typically operate on a continuous basis and create substantial noise levels during surgery thus potentially interfering with normal operating room dialogue.

Accordingly, electrosurgical instruments including integrated systems for aspirating the plume produced by the electrosurgical instruments during the electrosurgical procedures as well as for aspirating excess blood or bodily fluids prior to coagulating the remaining vessels have been developed. For example, electrosurgical instruments have been developed which include an aspirating system including a suction tube having at least one suction opening disposed in close proximity to the electrocautery tip (e.g., a blade, loop, etc.) a proximal end which is in fluid communication with a remote source of vacuum. In order to reduce the potential of the suction tube from becoming tangled or interfering with the movement of the operating staff around the operating room, the source of vacuum is placed close to the operative site thus keeping the suction tube shorter. As a result, the noise from the source of vacuum is also closer to the operative site and thus continues to potentially interfere with the normal operating room dialogue.

It is an object of the present disclosure to provide an electrosurgical pencil including a manual aspirator/irrigator.

It is another object of the present disclosure to provide an electrosurgical instrument including a self-contained manual aspirator/irrigator.

It is a further object of the present disclosure to provide an electrosurgical instrument having a manual aspirator/irrigator which effectively removes a plume

created during surgical procedures and which effectively delivers a fluid during the surgical procedures.

It is still a further object of the present disclosure to provide an electrosurgical instrument having a manual aspirator/irrigator which can deliver a quantity of irrigating solution and/or medicament during the surgical procedure.

These and other objects will be more clearly illustrated below by the description of the drawings and the detailed description of the preferred embodiments.

SUMMARY

The present disclosure is directed to an electrosurgical pencil having an aspirating/irrigating system. According to one aspect of the present disclosure, the electrosurgical pencil includes an elongate housing, an electrocautery blade supported within the housing and extending distally from the housing, the electrocautery blade being connected to a source of electrosurgical energy, and an activation button supported on the housing, the activation button being configured and adapted to complete a control loop extending from the source of electrosurgical energy upon actuation thereof. The electrosurgical pencil further includes an aspirating/irrigating system operatively connected to the housing, wherein the aspirating/irrigating system is configured and adapted to manually perform at least one of delivering a quantity of fluid to a target surgical site and withdrawing a quantity of fluid from the target surgical site.

It is envisioned that the aspirating/irrigating system includes a resilient or compliant handle which defines at least one chamber therein. The aspirating/irrigating system can further include a fluid passage extending between at least one chamber of the resilient handle and at least one aperture formed in a distal end of the housing. A quantity of fluid is contained within the at least one chamber of the resilient or compliant handle.

The handle has an expanded condition and is compressible to a non-expanded condition, wherein compression of the resilient handle causes the quantity of fluid contained in the at least one chamber of the resilient handle to be urged through the fluid passage and out of at least one aperture formed in the distal end of the housing. Accordingly, when the resilient handle is allowed to return to its expanded condition from the non-expanded condition, fluid is drawn into the at least one chamber of the resilient handle through the fluid passage and in through at least one aperture formed in the distal end of the housing.

The aspirating/irrigating system preferably further includes a valve disposed between at least one fluid passage and at least one fluid chamber. The valve is configured and adapted to allow fluid to pass from the chamber to the fluid passage when the resilient handle is compressed to a non-expanded condition. The aspirating/irrigating system preferably further includes a second valve disposed in fluid communication with a second chamber. The second valve is configured and adapted to

allow fluid to pass into the second chamber when the resilient handle is allowed to return to its expanded condition. The second valve is disposed between a second chamber in the handle and a second passage which communicates with at least one aperture at the distal end of the housing. Preferably, the resilient handle is fabricated rubber.

It is envisioned that the electrosurgical pencil further includes a mode selector supported on the housing, the mode selector being electrically connected to the source of electrosurgical energy and is configured and adapted to vary a waveform duty cycle which is delivered from the source of electrosurgical energy to the electrocautery blade. The mode selector is configured and adapted to vary the waveform duty cycle to produce at least one of a cutting, blending and coagulating effect.

In another embodiment, the aspirating/irrigating system includes a resilient handle and defines first and second chambers separated by a dividing member, and first and second fluid passages extending respectively between the first and second chambers of the resilient handle and the at least one aperture formed in a distal end of the housing. The handle has an expanded condition and is compressible to a non-expanded condition.

The aspirating/irrigating system includes a first valve disposed between the first fluid passage and the first chamber, a second valve disposed between the

second fluid passage and the second chamber, and a relief valve for equalizing the environmental conditions between the first and second chambers.

The first chamber preferably includes a quantity of fluid contained therein. The first valve is configured and adapted to allow the quantity of fluid contained in the first chamber to pass from the first chamber to the first fluid passage when the resilient handle is compressed to a non-expanded condition. The second valve is configured and adapted to allow fluid to be drawn into the second chamber when the resilient handle is allowed to return to the expanded condition from the non-expanded condition.

According to another aspect of the present disclosure, an electrosurgical pencil for selectively providing electrosurgical energy to tissue, the electrosurgical pencil having an electrosurgical blade electrically connected to the source of electrosurgical energy is provided. The electrosurgical pencil includes an elongate housing configured and adapted to receive the electrosurgical blade in a distal end thereof, and a self-contained, manual aspirating/irrigating system operatively connected to the housing. The aspirating/irrigating system includes a body portion defining at least one chamber therein, and a fluid passage extending between an aperture formed in a distal end of the housing and the at least one chamber, wherein the body portion has an expanded condition in which at least one chamber has a first volume and a non-expanded condition in which at least one chamber has a second volume which is less than the first volume.

The aspirating/irrigating system includes a first valve disposed between at least one chamber and the fluid passage, and a second valve disposed in the body portion and in fluid communication with at least one chamber. The first valve is configured and adapted to allow fluid to pass out of at least one chamber and the second valve is configured and adapted to allow fluid to enter at least one chamber.

At least one chamber of the body portion contains a quantity of fluid. Accordingly, when the body portion is compressed from the first volume to the second volume the quantity of fluid is urged out of one of the chambers through the first valve and when the body portion is allowed to return to the first volume from the second volume fluid enters a different one of the chambers from the second valve.

According to yet another aspect of the present disclosure, a method of aspirating/irrigating a target surgical site during an electrosurgical procedure is provided. The method includes the step of providing an electrosurgical pencil including an elongate housing, an electrocautery blade supported within the housing and extending distally from the housing, the electrocautery blade being connected to a source of electrosurgical energy, an activation button supported on the housing, the activation button being configured and adapted to complete a control loop extending from the source of electrosurgical energy upon actuation thereof, and an aspirating/irrigating system operatively connected to the housing, wherein the aspirating/irrigating system includes a resilient handle which is configured and adapted to at least one of deliver a quantity of fluid contained in the handle to a target surgical

site when the handle is compressed and withdraw a quantity of fluid from the target surgical site when the handle is allowed to expand.

The method further includes the steps of performing an electrocautery function at a target surgical site, and at least one of compressing the handle to deliver the quantity of fluid contained therein to the target surgical site and allowing the handle to expand to withdraw a quantity of fluid from the target surgical site.

It is envisioned that the aspirating/irrigating system includes a fluid passage extending between an aperture formed in a distal end of the housing and the at least one chamber.

With the handle at least partially compressed, the method further includes the step of placing the aperture in a quantity of fluid and allowing the handle to expand to withdraw fluid into the at least one chamber.

These and other features and advantages of the present disclosure will be readily apparent from the following drawings and detailed description of preferred embodiments.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are incorporated in and constitute a part of this specification, illustrate embodiments of the invention, and together with a general description of the invention given above, and the detailed description of the embodiments given below, serve to explain the principles of the invention.

FIG. 1 is a perspective view of an electrosurgical pencil in accordance with the present disclosure;

FIG. 2 is a side elevational view of the electrosurgical pencil of FIG. 1;

FIG. 3 is a top plan view of the electrosurgical pencil of FIG. 1;

FIG. 4 is a front elevational view of the electrosurgical pencil of FIG. 1;

FIG. 5 is a cross-sectional side elevational view of the electrosurgical pencil of FIG. 1 as taken through a longitudinal axis thereof;

FIG. 6 is a cross-sectional side elevational view of the electrosurgical pencil of FIG. 1, illustrating a first step in a mode of operation;

FIG. 7 is a cross-sectional side elevational view of the electrosurgical pencil of FIG. 1, illustrating a second step in the mode of operation;

FIG. 8A is a cross-sectional side elevational view of an electrosurgical pencil, according to another embodiment of the disclosure, illustrating a first step in a mode of operation;

FIG. 8B is a bottom cross-sectional view of the electrosurgical pencil of FIG. 8A taken through Y-Y of FIG. 8A;

FIG. 9 is a cross-sectional side elevational view of the electrosurgical pencil of FIG. 8, illustrating a second step in the mode of operation;

FIG. 10 is a cross-sectional side elevational view of the electrosurgical pencil, according to yet another embodiment of the present disclosure, illustrating a first step in a mode of operation;

FIG. 11 is a cross-sectional side elevational view of the electrosurgical pencil of FIG. 10, illustrating a second step in the mode of operation;

FIG. 12 is a bottom cross-sectional view of the electrosurgical pencil of FIG. 10 taken through X-X of FIG. 10; and

Fig. 13 is a side perspective view of an alternate embodiment according to the present disclosure wherein the aspiration ports are located on an electrode of the electrosurgical pencil.

DETAILED DESCRIPTION

Preferred embodiments of the presently disclosed electrosurgical pencil will now be described in detail with reference to the drawing figures wherein like reference numerals identify similar or identical elements. As used herein, the term “distal” refers to that portion which is further from the user while the term “proximal” refers to that portion which is closer to the user.

FIG. 1 sets forth a perspective view of an electrosurgical pencil constructed in accordance with one embodiment of the present disclosure and generally referenced by numeral 100. While the following description will be directed towards electrosurgical pencils it is envisioned that the features and concepts of the present disclosure can be applied to any electrosurgical type instrument.

As seen in FIGS. 1-5, electrosurgical pencil 100 includes an elongate housing 102 configured and adapted to support a blade receptacle 104 at a distal end 103 thereof which, in turn, receives a replaceable electrocautery end effector 106 in the form of a loop and/or blade therein. The term electrocautery blade, as used herein, is understood to include a planar blade, a loop (as shown in FIGS. 1-5), a needle, etc. A distal end portion 108 of blade 106 extends distally from receptacle 104 while a

proximal end portion 110 (see FIG. 5) is retained within distal end 103 of housing 102. It is contemplated that electrocautery blade 106 is fabricated from a conductive type material, such as, for example, stainless steel, or is coated with an electrically conductive material.

As shown in FIG. 1, electrosurgical pencil 100 is coupled to a conventional electrosurgical generator "G" via a cable 112. Cable 112 includes a transmission wire (see FIG. 5) which electrically interconnects electrosurgical generator "G" with the proximal end portion of electrocautery blade 106. Cable 112 further includes a control loop 116 which electrically interconnects activation buttons, supported on an outer surface 107 of housing 102, with electrosurgical generator "G".

Reference is made to commonly assigned U.S. Provisional Patent No. 60/413,410 filed September 25, 2002; U.S. Provisional Patent No. 60/424,352 filed November 5, 2002; and U.S. Provisional Patent No. 60/448,520 filed February 20, 2003, the entire contents of each of which are incorporated herein by reference, for a more detailed explanation and for alternative configurations of control loop 107.

By way of example only, electrosurgical generator "G" may be any one of the following, or equivalents thereof: the "FORCE FX", "FORCE 2" or "FORCE 4" generators manufactured by Valleylab, Inc., a division of Tyco Healthcare, LP, located in Boulder, Colorado. Preferably, electrosurgical generator "G" can be variable in order to provide appropriate first RF signals (e.g., 1 to 120 watts) for tissue cutting and

appropriate second RF signals (e.g., 1 to 300 watts) for tissue coagulation. Generator “G” may also include a “blend” mode.

Preferably, an exemplary electrosurgical generator “G” is disclosed in commonly assigned U.S. Patent No. 6,068,627 to Orszulak, et al., the entire contents of which is hereby incorporated by reference. The electrosurgical generator disclosed in the ‘627 patent includes, *inter alia*, an identifying circuit and a switch therein. In general, the identifying circuit is responsive to information received from a generator and transmits a verification signal back to the generator. Meanwhile, the switch is connected to the identifying circuit and is responsive to signaling received from the identifying circuit.

Turning back to FIGS. 1-5, as mentioned above, electrosurgical pencil 100 further includes at least one activation button 124 supported on outer surface 107 of housing 102. Activation button 124 is operatively connected to a switch 126 which, in turn, controls the transmission of RF electrical energy supplied from generator “G” to electrosurgical blade 106, in the manner of an on/off switch. More particularly, switch 126 is electrically coupled to control loop 116 and is configured to close and/or complete control loop 116 to thereby permit RF energy to be transmitted to electrocautery blade 106 from electrosurgical generator “G”. It is envisioned that activation button 124 may be multi-positionable such that a “low” setting and a “high” setting for each mode is available to the surgeon for each mode.

Electrosurgical pencil 100 further includes at least one mode selector 128 operatively supported on housing 102. Mode selector 128 is configured and adapted to enable the surgeon to set electrosurgical pencil 100 to one of a number of discrete modes of operation, such as, for example, cutting, blending and/or coagulating. As seen in FIG. 2, mode selector 128 can be rotated in the directions indicated by double-headed arrow "X" from a first position, in which electrosurgical pencil 100 is set to transmit a cutting "waveform duty cycle" to electrocautery blade 106, to a second position, in which electrosurgical pencil 100 is set to transmit a blending "waveform duty cycle" to electrocautery blade 106, and to a third position, in which electrosurgical pencil 100 is set to transmit a coagulating "waveform duty cycle" to electrocautery blade 106.

It is contemplated that mode selector 128 may be provided with a series of cooperating discrete positions defining a series of positions, preferably three, to allow easy selection of the mode of operation of electrosurgical pencil 100 between, for example, cutting, blending and coagulating. The series of cooperating discrete or detented positions also provide the surgeon with a degree of tactile feedback.

Electrosurgical pencil 100 further includes a manual aspirating/irrigating system 140 operatively connected to a proximal end of housing 102. Aspirating/irrigating system 140 includes a handle or body portion 142 preferably fabricated from a resilient or substantially compliant material, such as, for example, rubber, and defines a hollow chamber 144 therein (see FIG. 5). Handle 142 is preferably shaped and sized to substantially fit in the palm of a surgeon's hand.

Aspirating/irrigating system 140 further includes at least one fluid passage 146 extending between chamber 144 of handle 142 and aperture(s) 148 formed in at least one of a side surface 104a of blade receptacle 104 (see FIGS. 1-3 and 5), a distal surface 104b of blade receptacle 104 (see FIGS. 1 and 4) and distal end 103 of housing 102 (see FIGS. 1 and 4).

Handle 142 has a fully expanded condition and a plurality of non-expanded conditions when handle 142 is squeezed and/or compressed an amount by the surgeon. In the fully expanded condition, chamber 144 of handle 142 defines a first volume, while in one of its plurality of non-fully expanded conditions, chamber 144 of handle 142 defines a plurality of second volumes, each of which are less than the first volume. In this manner, when handle 142 is in one of the plurality of second volumes and then released, handle 142 creates a suction force at aperture(s) 148, through fluid passage 146.

When handle 142 is urged from its fully expanded condition to its non-fully expanded condition (i.e., to at least partially evacuate chamber 144), a fluid "F", contained within chamber 144 of handle 142, is urged and/or squeezed through fluid passage 146 and out through aperture(s) 148. When handle 142 is allowed to return to its fully expanded condition, from its non-fully expanded condition, (i.e., as by allowing resilient handle 142 to overcome the squeezing and/or compressing forces and to return to its fully expanded condition), as described above, a suction is created at apertures 148, through fluid passage 146, to withdraw fluid "F" into chamber 144. As used herein,

and in no way is it to be considered limiting, the term fluid is understood to include air, water, saline, medicament, body fluid, blood, lymph fluid, smoke, etc.

In operation and depending on the particular electrosurgical function desired (e.g. cutting, blending or coagulating), the surgeon manipulates, e.g., rotates, mode selector 128 in direction "X" until the desired electrosurgical function is selected. The surgeon then depresses activation button 124, in the direction indicated by arrow "Y" (see FIGS. 2 and 5) thereby closing switch 126 and closing and/or completing control loop 116. In turn, generator "G" transmits an appropriate waveform output to electrocautery blade 106 via transmission wire 114.

Preferably, as seen throughout the figures, activation button 124 and mode selector 128 are supported in a recess or depression 109 formed in outer wall 107 of housing 102. Desirably, activation button 124 is positioned at a location where the fingers of the surgeon would normally rest when electrosurgical pencil 100 is held in the hand of the surgeon while mode selector 128 is placed at a location which would not be confused with activation button 124.

Moreover, depending on the particular electrosurgical procedure being performed, the stage of the procedure and the resulting effects created by electrocautery blade 106 on the body tissue, the surgeon may desire or be required to manipulate aspirating/irrigating system 140. For example, fluid produced by the body and located at the surgical site (e.g., blood, lymph fluid, etc.) during the surgical

procedure can be aspirated from the surgical site using electrosurgical pencil 100. Aspiration of fluid from the surgical site can be achieved, for example with chamber 144 of handle 142 empty, by the surgeon initially squeezing and/or compressing handle 142 to at least partially evacuate chamber 144, placing aperture(s) 148 in or near a quantity of fluid "F", and allowing handle 142 to expand causing the vacuum of chamber 144 to withdraw fluid from the surgical site into chamber 144 through fluid passage 146.

The aspiration step can be repeated, without first evacuating chamber 144 of fluid "F" contained therein, by first orienting and/or tilting electrosurgical pencil 100 to a position where fluid "F" contained in chamber 144 does not cover, as seen in FIG. 6, an interface 150 between chamber 144 and fluid passage 146, squeezing and/or compressing handle 142, placing aperture(s) 148 in fluid at the surgical site, and allowing handle 142 to expand.

In addition, during the surgical procedure, it may be desired or necessary to irrigate the surgical site with a fluid "F". Irrigation of the surgical site with fluid "F", can be achieved by orienting and/or tilting electrosurgical pencil 100 to a position where fluid "F", contained in chamber 144, covers (see FIG. 7) an interface 150 between chamber 144 and fluid passage 146 and by then squeezing and/or compressing handle 142 to expel a quantity of fluid "F" therefrom. It is contemplated that fluid "F" expelled from electrosurgical pencil 100 can be a saline solution for rinsing the surgical site clean or, alternatively, a medicament for treating the surgical site. Examples of medicaments

which can be delivered by electro-surgical pencil 100 include, and are not limited to: coagulants; hemostats; sealants; adhesives and the like.

It is contemplated that aspirating/irrigating system 140 can include a control switch 152 incorporated into handle 142 and connected to chamber 144 and a valve 154 disposed at interface 150, between fluid passage 146 and chamber 144. Preferably, valve 154 is a one-way check-type valve which cooperates with control switch 152 to permit a uni-directional flow of fluid either into (or out of) chamber 144 through fluid passage 146 depending upon a particular purpose.

As best seen in FIG. 8A and 8B, it is also envisioned that the aspirating/irrigating system 140 may include two check valves 154 and 155 which are mechanically coupled between fluid passage 146 and two chambers 144a' and 144b', respectively. A divider 143 is disposed between chambers 144a' and 144b'. In this instance, fluid from chamber 144b' is utilized to irrigate that surgical site and the suction created upon irrigation (i.e., upon squeezing handle 142) is utilized to aspirate the surgical site and return surgical waste to chamber 144a' when handle 142 is released. Each check valve 154 and 155 is set up to allow passage in one direction to accomplish this purpose.

A relief valve may be utilized to restore environmental equilibrium between the two chambers 144a' and 144b' after each irrigation/aspiration cycle. Alternatively, control switch 152 may be utilized with a single check valve which allows selective flow

into the chamber or out of the chamber upon activation. As can be appreciated, more than one check valve may be utilized for this purpose, i.e., a first check valve 144a' for storing liquid and contaminants from the surgical site and a second check valve 144b' for storing irrigation fluid (see FIG. 12). In this instance, two different fluid passages would be employed. This is discussed in greater detail below.

In one method of use, as seen in FIG. 7, valve 154 can be configured to allow electrosurgical pencil 100 to simply irrigate the surgical site. Accordingly, fluid can only flow out of chamber 144 when handle 142 squeezed (see arrow "B"). More particularly, when handle 142 is squeezed/compressed to a non-expanded condition, fluid "F", contained in chamber 144, is expelled from electrosurgical pencil 100 through valve 154 and fluid passage 146. When handle 142 is allowed to return to its expanded condition, no fluid from the surgical site is drawn into chamber 144 through valve 154.

In another method of use, valve 154 can be configured to allow electrosurgical pencil 100 to simply aspirate the surgical site. In this manner, when handle 142 is squeezed/compressed to its non-expanded condition, air is expelled from chamber 144 through a relief valve 157 (see FIG. 6) when handle 142 is depressed and when handle 142 is allowed to return to its expanded condition fluid from the surgical site is drawn into chamber 144 through valve 154 and fluid passage 146.

It is contemplated that using valve 154 (or multiple valves) enables electrosurgical pencil 100 to be oriented in any direction when performing an aspirating

function. However, when performing the irrigating function, in order for fluid "F" to be expelled from chamber 144 upon squeezing/compressing of handle 146, electrosurgical pencil 100 needs to be oriented such that valve 154 is at least partially covered by fluid "F" contained within chamber 144.

It is further envisioned that aspirating/irrigating system 140 can be provided with an additional valve (not shown) which can be used to empty chamber 144 if filled with fluid from the surgical site and/or refill chamber 144 with fluid "F" if emptied. In this manner, if a different type of fluid "F" is desired to be contained in chamber 144 for use during the surgical procedure, chamber 144 can be filled accordingly.

It is further envisioned that aspirating/irrigating system 140 can be removed from housing 102 and replaced with a new aspirating/irrigating system 140. In this manner, when chamber 144 has been filled with fluid from the surgical site or emptied of fluid "F" originally contained therein, used aspirating/irrigating system 140 can be replaced with a new aspirating/irrigating system 140. Moreover, new aspirating/irrigating system 140 can be provided with a different fluid "F" contained therein which different fluid "F" is selected by the surgeon according to the properties desired.

Turning now to FIGS. 10-12, in an alternative embodiment, electrosurgical pencil 100 includes an aspirating/irrigating system 140' operatively connected to a proximal end of housing 102. Aspirating/irrigating system 140' includes a resilient

handle 142' having a pair of hollow chambers 144a', 144b' (e.g., a fluid collecting chamber and a fluid dispensing chamber) separated by a resilient dividing wall 143'. Aspirating/irrigating system 140' further includes a pair of fluid passages 146a, 146b extending, one each, between chambers 144a', 144b' of handle 142' and respective aperture(s) 148' formed in at least one of a side surface 104a of blade receptacle 104 (see FIGS. 1-3 and 5), a distal surface 104b of blade receptacle 104 (see FIGS. 1 and 4) and distal end 103 of housing 102 (see FIGS. 1 and 4). For the sake of simplicity, aperture(s) 148' are shown formed in distal end 103 of housing 102 only.

As seen in FIGS. 10-12, aspirating/irrigating system 140' further includes a series of valves, preferably three, operatively associated therewith. In one embodiment, a first valve 160 is disposed between fluid passage 146a and chamber 144a', a second valve 162 is disposed between fluid passage 146b and chamber 144b', and an air relief valve 164 is disposed in a dividing wall 143 separating chamber 144a' from chamber 144b'.

In one method of use, first valve 160 is set such that fluid "F" can only flow out of chamber 144a' (as indicated by arrow "B") when handle 142' is squeezed/compressed to its non-expanded condition, while second valve 162 is set such that fluid from the surgical site can only flow into chamber 144b' (as indicated by arrow "A") when handle 142' is allowed to return to its expanded condition. Meanwhile, third valve 164 is set such that fluid (e.g., air) can only flow from chamber 144b' to chamber 144a' (as indicated by arrow "C"). In this manner, when handle 142' is

squeezed/compressed to a non-expanded condition, first valve 160 allows fluid “F” to be expelled from electrosurgical instrument 100 through fluid passage 146a, second valve 162 prevents fluid from the surgical site from being expelled from electrosurgical instrument 100 through fluid passage 144b’, and relief valve 164 allows passage of air from chamber 144b’ to chamber 144a’. Accordingly, the vacuum created within chamber 144a’ by the squeezing/compressing of handle 142’ is at least partially distributed, preferably equally distributed, between chambers 144a’ and 144b’ via relief valve 164 (i.e., chambers 144a’ and 144b’ are in equilibrium or equilibrated). As such, when handle 142’ is allowed to return to its expanded condition, relief valve 164 disposed between chambers 144a’ and 144b’ returns the equilibrium between chambers 144b’ and 144a’.

The process is repeated as many times as needed until either chamber 144a’ has been emptied of fluid “F” contained therein or until chamber 144b’ has been filled with fluid from the surgical site. It is contemplated that each of chambers 144a’ and 144b’ can be provided with an additional valve (not shown). Preferably, the additional valve for chamber 144a’ can be used to refill chamber 144a’ with fluid “F” after chamber 144a’ has been at least partially emptied during the surgical procedure. The additional valve for chamber 144b’ can be used to empty chamber 144b’ of fluid from the surgical site after chamber 144b’ has been at least partially filled during the surgical procedure.

In an alternative embodiment, it is envisioned that aspirating/irrigating system 140' can be removed from housing 102 and replaced by another or a replacement aspirating/irrigating system 140'. In this manner, when chamber 144a' has been emptied of fluid "F" and/or chamber 144b' has been filled with fluid from the surgical site a new aspirating/irrigating system 140' can be attached to housing 102 as or when needed. Moreover, if a different fluid "F", to be expelled from electrosurgical pencil 100, is desired to be used by the surgeon, a new aspirating/irrigating system 140' containing a different fluid "F" is attached to housing 102 of electrosurgical pencil 100.

Fig. 13 shows an alternate embodiment of the present disclosure wherein the fluid dispensing apertures or the aspiration/suction ports 148 are located on the electrode 106 as compared to the apertures shown in Fig. 1 wherein the apertures are located on the blade support 104. Fig. 13 also shows that the fluid dispensing apertures or aspiration/suction ports 148 may also be disposed at the distal-most tip 103 of the distal end of the housing 102

Although the presently-illustrated embodiments of the preset disclosure show electrosurgical pencils for use with the manual aspirator / irrigator as described herein, it is also contemplated that the manual aspirator / irrigator may be configured for use with other surgical devices, e.g., laparoscopes, coagulators, vessel sealers, ultrasonic devices etc.

It is also envisioned that the presently disclosed aspirator / irrigator may include a hard handle with a compliant pump or bladder disposed therein. A user would successively pump the bladder or pump to dispense or suction fluid to or from the operating site.

While embodiments of electrosurgical pencils according to the present disclosure have been described herein, it is not intended that the disclosure be limited there and that the above description should be construed as merely exemplifications of preferred embodiments. Those skilled in the art will envision other modifications within the scope and spirit of the present disclosure.
